

1 Object Oriented Programming

In a previous lecture, you were introduced to the programming paradigm known as Object-Oriented Programming (OOP). OOP allows us to treat data as objects - like we do in real life.

For example, consider the **class** `Student`. Each of you as individuals are an **instance** of this class. So, a student `Angela` would be an instance of the class `Student`.

Details that all CS 61A students have, such as `name`, `year`, and `major`, are called **instance attributes**. Every student has these attributes, but their values differ from student to student. An attribute that is shared among all instances of `Student` is known as a **class attribute**. An example would be the `instructors` attribute; the instructors for CS 61A, James, Jen, Mitas and Tammy, are the same for every student in CS 61A.

All students are able to do homework, attend lecture, and go to office hours. When functions belong to a specific object, they are said to be **methods**. In this case, these actions would be bound methods of `Student` objects.

Here is a recap of what we discussed above:

- **class:** a template for creating objects
- **instance:** a single object created from a class
- **instance attribute:** a property of an object, specific to an instance
- **class attribute:** a property of an object, shared by all instances of a class
- **method:** an action (function) that all instances of a class may perform

Questions

- 1.1 Below we have defined the classes `Instructor`, `Student`, and `TeachingAssistant`, implementing some of what was described above. Remember that we pass the `self` argument implicitly to instance methods when using dot-notation. There are more questions on the next page.

```
class Instructor:
    degree = "PhD (Magic)" # this is a class attribute
    def __init__(self, name):
        self.name = name # this is an instance attribute

    def lecture(self, topic):
        print("Today we're learning about " + topic)
```

```
dumbledore = Instructor("Dumbledore")
```

```
class Student:
    instructor = dumbledore

    def __init__(self, name, ta):
        self.name = name
        self.understanding = 0
        ta.add_student(self)

    def attend_lecture(self, topic):
        Student.instructor.lecture(topic)
        if Student.instructor == dumbledore:
            print(Student.instructor.name + " is awesome!")
        else:
            print("I miss Dumbledore.")
        self.understanding += 1

    def visit_office_hours(self, staff):
        staff.assist(self)
        print("Thanks, " + staff.name)
```

```
class TeachingAssistant:
    def __init__(self, name):
        self.name = name
        self.students = {}

    def add_student(self, student):
        self.students[student.name] = student

    def assist(self, student):
        student.understanding += 1
```

What will the following lines output?

```
>>> snape = TeachingAssistant("Snape")
>>> harry = Student("Harry", snape)
>>> harry.attend_lecture("potions")
```

```
Today we're learning about potions
Dumbledore is awesome!
```

```
>>> harry.visit_office_hours(TeachingAssistant("Hagrid"))
```

```
Thanks, Hagrid
```

```
>>> harry.understanding
```

```
2
```

```
>>> [name for name in snape.students]
```

```
['Harry']
```

```
>>> Student.instructor = Instructor("Umbridge")
>>> Student.attend_lecture(harry, "transfiguration")
# Equivalent to harry.attend_lecture("transfiguration")
```

```
Today we're learning about transfiguration
I miss Dumbledore.
```

- 1.2 We now want to write three different classes, `Mailman`, `Client`, and `Email` to simulate email. Fill in the definitions below to finish the implementation! There are more methods to fill out on the next page.

class `Email`:

```
    """Every email object has 3 instance attributes: the
    message, the sender name, and the recipient name.
    """
```

```
    def __init__(self, msg, sender_name, recipient_name):
```

```
        self.msg = msg
        self.sender_name = sender_name
        self.recipient_name = recipient_name
```

class `Mailman`:

```
    """Each Mailman has an instance attribute clients, which
    is a dictionary that associates client names with
    client objects.
    """
```

```
    def __init__(self):
        self.clients = {}
```

```
    def send(self, email):
        """Take an email and put it in the inbox of the client
        it is addressed to.
        """
```

```
        client = self.clients[email.recipient_name]
        client.receive(email)
```

```
    def register_client(self, client, client_name):
        """Takes a client object and client_name and adds it
        to the clients instance attribute.
        """
```

```
        self.clients[client_name] = client
```

```

class Client:
    """Every Client has instance attributes name (which is
    used for addressing emails to the client), mailman
    (which is used to send emails out to other clients), and
    inbox (a list of all emails the client has received).
    """

    def __init__(self, mailman, name):
        self.inbox = []

        self.mailman = mailman
        self.name = name
        self.mailman.register_client(self, self.name)

    def compose(self, msg, recipient_name):
        """Send an email with the given message msg to the
        given recipient client.
        """

        email = Email(msg, self.name, recipient_name)
        self.mailman.send(email)

    def receive(self, email):
        """Take an email and add it to the inbox of this
        client.
        """

        self.inbox.append(email)

```

2 Inheritance

Python classes can implement a useful abstraction technique known as **inheritance**. To illustrate this concept, consider the following `Dog` and `Cat` classes.

```
class Dog(object):
    def __init__(self, name, owner):
        self.is_alive = True
        self.name = name
        self.owner = owner
    def eat(self, thing):
        print(self.name + " ate a " + str(thing) + "!")
    def talk(self):
        print(self.name + " says woof!")
```

```
class Cat(object):
    def __init__(self, name, owner, lives=9):
        self.is_alive = True
        self.name = name
        self.owner = owner
        self.lives = lives
    def eat(self, thing):
        print(self.name + " ate a " + str(thing) + "!")
    def talk(self):
        print(self.name + " says meow!")
```

Notice that because dogs and cats share a lot of similar qualities, there is a lot of repeated code! To avoid redefining attributes and methods for similar classes, we can write a single **superclass** from which the similar classes **inherit**. For example, we can write a class called `Pet` and redefine `Dog` as a **subclass** of `Pet`:

```
class Pet(object):
    def __init__(self, name, owner):
        self.is_alive = True    # It's alive!!!
        self.name = name
        self.owner = owner
    def eat(self, thing):
        print(self.name + " ate a " + str(thing) + "!")
    def talk(self):
        print(self.name)

class Dog(Pet):
    def talk(self):
        print(self.name + ' says woof!')
```

Inheritance represents a hierarchical relationship between two or more classes where one class *is a* more specific version of the other, e.g. a dog *is a* pet. Because `Dog` inherits from `Pet`, we didn't have to redefine `__init__` or `eat`. However, since we want `Dog` to `talk` in a way that is unique to dogs, we did **override**, the `talk` method.

Questions

- 2.1 Below is a skeleton for the `Cat` class, which inherits from the `Pet` class. To complete the implementation, override the `__init__` and `talk` methods and add a new `lose_life` method.

Hint: You can call the `__init__` method of `Pet` to set a cat's name and owner.

```
class Cat(Pet):
    def __init__(self, name, owner, lives=9):

        Pet.__init__(self, name, owner)
        self.lives = lives

    def talk(self):
        """ Print out a cat's greeting.

        >>> Cat('Thomas', 'Tammy').talk()
        Thomas says meow!
        """

        print(self.name + ' says meow!')

    def lose_life(self):
        """Decrements a cat's life by 1. When lives reaches zero, 'is_alive'
        becomes False.
        """

        if self.lives > 0:
            self.lives -= 1
            if self.lives == 0:
                self.is_alive = False
        else:
            print("This cat has no more lives to lose :(")
```

[Video walkthrough](#)

- 2.2 More cats! Fill in this implementation of a class called `NoisyCat`, which is just like a normal `Cat`. However, `NoisyCat` talks a lot – twice as much as a regular `Cat`!

```
class _____: # Fill me in!
```

```

class NoisyCat(Cat):

    """A Cat that repeats things twice."""
    def __init__(self, name, owner, lives=9):
        # Is this method necessary? Why or why not?

        Cat.__init__(self, name, owner, lives)

```

No, this method is not necessary because NoisyCat already inherits Cat's `__init__` method

```

def talk(self):
    """Talks twice as much as a regular cat.

    >>> NoisyCat('Magic', 'James').talk()
    Magic says meow!
    Magic says meow!
    """

    Cat.talk(self)
    Cat.talk(self)

```

Extra Questions

2.3 (Summer 2013 Final) What would Python display?

```

class A:
    def f(self):
        return 2
    def g(self, obj, x):
        if x == 0:
            return A.f(obj)
        return obj.f() + self.g(self, x - 1)

class B(A):
    def f(self):
        return 4

>>> x, y = A(), B()
>>> x.f()

```

2

```
>>> B.f()
```

```
Error (missing self argument)
```

```
>>> x.g(x, 1)
```

4

```
>>> y.g(x, 2)
```

8

[Video walkthrough](#)

- 2.4 (Summer 2013 Final) Implement the `Foo` class so that the following interpreter session works as expected.

```
>>> x = Foo(1)
```

```
>>> x.g(3)
```

4

```
>>> x.g(5)
```

6

```
>>> x.bar = 5
```

```
>>> x.g(5)
```

10

```
class Foo:
```

```
    def __init__(self, bar):
```

```
        self.bar = bar
```

```
    def g(self, n):
```

```
        return self.bar + n
```
