Idea: All bank accounts have a balance and an account holder;
 the Account class should add those attributes to each of its instances
                            >>> a = Account('Jim')
                            >>> a.holder
                            'Jim'
                            >>> a.balance
                                                      An account instance
                                                                holder: 'Jim'
                                                 balance: 0
1.A new instance of that class is created:
        _init__ method of the class is called with the new object as its first
  argument (named self), along with any additional arguments provided in the
                       class Account:
                                __init__(self, account_holder):
self.balance = 0
                           >def
                                 self.holder = account_holder
                                deposit(self, amount):
                                _self.balance = self.balance + amount return self.balance
                                withdraw(self, amount):
if amount > self.balance:
    return 'Insufficient funds'
                            def
                                 self.balance = self.balance - amount
                                 return self.balance
                         >>> type(Account.deposit)
                        <class 'function
                         >>> type(a.deposit)
                         <class 'method'
                         >>> Account.deposit(a, 5)
                         >>> a.deposit(2)
                                                       Call expression
                               Dot expression
                              <expression> . <name>
 The <expression> can be any valid Python expression.
 The <name> must be a simple name.
 Evaluates to the value of the attribute looked up by <name> in the object
 that is the value of the <expression>.
 To evaluate a dot expression:

1. Evaluate the <expression> to the left of the dot, which yields
      the object of the dot expression
      <name> is matched against the instance attributes of that object;
     if an attribute with that name exists, its value is returned If not, <name> is looked up in the class, which yields a class
     That value is returned unless it is a function, in which case a
     bound method is returned instead
 Assignment statements with a dot expression on their left-hand side affect
 attributes for the object of that dot expression
  • If the object is an instance, then assignment sets an instance attribute
  • If the object is a class, then assignment sets a class attribute
                                interest: 0.02 0.04 0.05 (withdraw, deposit, __init
