1 OOP

1. **(H)OOP**

```
Given the following code, what will Python output for the following prompts?
class Baller:
    all_players = []
    def __init__(self, name, has_ball = False):
       self.name = name
       self.has_ball = has_ball
       Baller.all_players.append(self)
    def pass_ball(self, other_player):
       if self.has_ball:
          self.has_ball = False
          other_player.has_ball = True
          return True
       else:
          return False
class BallHog(Baller):
    def pass_ball(self, other_player):
```

return False

- >>> alex = Baller('Alex', True)
 >>> mitas = BallHog('Mitas')
- >>> len(Baller.all_players)

Solution: 2

>>> Baller.name

Solution: Error

>>> **len**(mitas.all_players)

Solution: 2

>>> alex.pass_ball()

Solution: Error

>>> alex.pass_ball(mitas)

Solution: True

>>> alex.pass_ball(mitas)

Solution: False

>>> BallHog.pass_ball(mitas, alex)

Solution: False

>>> mitas.pass_ball(alex)

Solution: False

>>> mitas.pass_ball(mitas, alex)

Solution: Error

2. Write TeamBaller, a subclass of Baller. An instance of TeamBaller cheers on the team every time it passes a ball.

```
Solution:
class TeamBaller(Baller):
    >>> cheerballer = TeamBaller('Chris', has_ball=True)
    >>> cheerballer.pass_ball(mitas)
    Yay!
    True
    >>> cheerballer.pass_ball(mitas)
    I don't have the ball
    False
    11 11 11
    def pass_ball(self, other):
        did_pass = Baller.pass_ball(self, other)
        if did_pass:
            print('Yay!')
        else:
            print('I don't have the ball')
        return did_pass
```

3. Lets use OOP to help us implement our good friend, the ping-pong sequence!

As a reminder, the ping-pong sequence counts up starting from 1 and is always either counting up or counting down.

At element k, the direction switches if k is a multiple of 7 or contains the digit 7.

The first 30 elements of the ping-pong sequence are listed below, with direction swaps marked using brackets at the 7th, 14th, 17th, 21st, 27th, and 28th elements:

```
1 2 3 4 5 6 [7] 6 5 4 3 2 1 [0] 1 2 [3] 2 1 0 [-1] 0 1 2 3 4 [5] [4] 5 6
```

Assume you have a function has_seven (k) that returns True if k contains the digit 7.

```
Solution:
    class PingPongTracker:
        def __init__(self):
            self.current = 0
            self.index = 1
            self.add = True

    def next(self):
        if self.add:
            self.current += 1
        else:
            self.current -= 1
        if has_seven(self.index) or self.index % 7 == 0:
            self.add = not self.add
        self.index += 1
        return self.current
```

4. **Flying the cOOP** What would Python display? Write the result of executing the code and the prompts below. If a function is returned, write "Function". If nothing is returned, write "Nothing". If an error occurs, write "Error".

```
class Bird:
   def __init__(self, call):
        self.call = call
        self.can_fly = True
   def fly(self):
        if self.can_fly:
            return "Don't stop me now!"
        else:
            return "Ground control to Major Tom..."
   def speak(self):
        print(self.call)
class Chicken(Bird):
   def speak(self, other):
        Bird.speak(self)
        other.speak()
class Penguin(Bird):
   can_fly = False
   def speak(self):
        call = "Ice to meet you"
        print (call)
andre = Chicken("cluck")
gunter = Penguin("noot")
```

GROUP TUTORING HANDOUT 7: OOP >>> andre.speak(Bird("coo")) Solution: cluck coo >>> andre.speak() Solution: Error >>> gunter.fly() **Solution:** "Don't stop me now!" >>> andre.speak(gunter) Solution: cluck Ice to meet you

>>> Bird.speak(gunter)

Solution: noot

2 Mutable Trees

Now that we know how to create objects using Python's class system, we have a new way of implementing some of the ADTs we saw earlier in the course. This allows us to reassign attributes of that object any time we want!

Here's an example of implementing trees using a class.

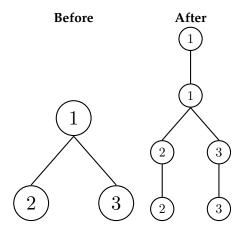

```
class Tree:
    def __init__(self, label, branches=[]):
        self.label = label
        self.branches = branches
    def is_leaf(self):
        return not self.branches
Here's how we might use this class:
>>> t = Tree(1, [Tree(2)])
>>> t.label
1
>>> t.label = 2
>>> t.label
>>> t.branches = t.branches + [Tree(3)]
>>> [b.label for b in t.branches]
[2, 3]
>>> t.branches[1].is leaf()
```

5. Implement tree_sum which takes in a Tree object and replaces the label of the tree with the sum of all the values in the tree_sum should also return the new label.

```
def tree_sum(t):
    """
    >>> t = Tree(1, [Tree(2, [Tree(3)]), Tree(4)])
    >>> tree_sum(t)
    10
    >>> t.label
    10
    >>> t.branches[0].label
    5
    >>> t.branches[1].label
    4
    """
```

```
Solution:
    for b in t.branches:
        t.label += tree_sum(b)
    return t.label
```

6. DoubleTree hired you to architect one of their hotel expansions! As you might expect, their floor plan can be modeled as a tree and the expansion plan requires doubling each node (the patented double tree floor plan). Here's what some sample expansions look like:

Fill in the implementation for double_tree.

```
def double_tree(t):
    """
    Given a tree, mutate it such that each entry appears
    twice.
    >>> t = Tree(1)
    >>> double_tree(t)
    >>> t.label
    1
    >>> t.branches[0].label
    1
    """
```

```
Solution:
    if t.is_leaf():
        t.branches = [Tree(t.label)]
    else:
        for b in t.branches:
            double_tree(b)
        t.branches = [Tree(t.label, t.branches)]
```
